ABSTRACT

A library for use by the computer aided design system, known as the Control System Design Environment, made up of hardware and software primitives of the Intel 8086 microprocessor family, was written to extend the capabilities of the design system to more than two microprocessor families. Compatibility between this library and the Intel 8080 library was desired and achieved by use of designs originally realized with the 8080 library.

I would like to thank my advisor, Professor Herschel Loomis, Jr., and second reader, Lieutenant Colonel Alan Ross, for their guidance during this project.

I. INTRODUCTION

Computer Aided Design has seen an upsurge of use in the past decade, providing assistance in the design and eventual realization of everything from Very Large Scale Integration circuits to complete systems. The use of computers to simplify man's tasks is the chief motivating factor to develop more powerful computing devices. Recent trends in the development of Computer Aided Design (CAD) tools are toward a more 'user friendly' environment. Some CAD systems are so sophisticated that the user need not know the underlying principles of design in order to take a given concept, from its inception through actual realization in terms of either hardware and/or software. Starting with the simplest of descriptions, today's system or component designers may very well spend all his/her time designing at a computer keyboard or digitizing table.

What motivates the trend toward more efficient design systems are threefold: 1) greater speed in producing a viable design, 2) better use of scarce design system resources, and 3) decreased cost to produce the desired item. With the introduction of the microprocessor, it became apparent that its uses were limitless. Any conceivable electronic application spurred its use. From general purpose computing to specialized repetitive

functions the microprocessor found its way into industrial, commercial and military applications. As more uses were found, the ability to design with these devices lagged behind the rising requests for these new designs. Since the designs are labor intensive and design engineering expertise is at a premium, the concept of computer aided design was born. This technique helps to pare down the time it takes to design a new system or component. Engineers were, of course, not the only item in short supply. Computers needed to aid in these designs were also a scarce commodity. This led to the improvement of the design tools to see a design to completion with the least amount of resources used (e.g. time, computer use etc) [Ref. 1]. Once these major impediments had been overcome, the ability for the computer to help optimize the design was at hand. Factors to be considered were to decrease the number of chips or silicon acreage, decrease the power requirements, and decrease the overall cost of the system.

The use of microprocessors for real time control is just one of the applications that is seen in today's electronic environment. As in the past, design of these systems are a time consuming and complex process. In order for digital computing systems to provide a design environment, an examination of just how a design engineer might approach the problem is justified. The designer must

rely on a certain amount of background knowledge of the problem that is presented prior to his attempting its design. The implementation of this knowledge may be by the use of a database of design rules. These rules would apply to both the hardware and software factors required to realize a given problem. An extension of this idea would be the creation of a sequential listing of all possible combinations of circuit devices or software tasks that may be necessary to construct a device and the tasking of the digital computer to maintain a running list of attributes to insure that all design criteria are being met in the generation of a design realization.

This thesis will provide a library of hardware and software primitives implemented using the Intel Corporation iAPX 86/10 (8086) 16-bit microprocessor and its family of support chips. Chapter II will discuss the origins of the design environment in which this library will be used and its current implementation. A description of the structure of the realization library is presented in Chapter III. Chapter IV introduces the 8086 microprocessor and discusses its memory organization, the basic hardware design of a system implemented in this library, and a complete discussion of the software configuration including the use of assemblers, control, and arithmetic processes. Chapter V outlines the testing of this library. Finally, Chapter VI offers some recommendations for system improvement, observations and conclusions.

II. BACKGROUND

The system model proposed by Matelan [Ref. 2] for the design of microprocessor based controllers contains a concept of computer aided design whereby the specifications are not initially linked to the type of technology that might be used to implement a system. This binding of the design to a particular hardware and software technology is performed only after several intermediate processes are executed. These intermediate functions build symbol and timing tables, and prepare a table of the individual primitive names required to realize the design. It is only after this, that an implementation technology is chosen. The technology is contained in a volume of hardware and software primitives called the realization library.

A. CONTROL SYSTEM DESIGN LANGUAGE

Matelan's proposal suggests the use of a new high level language which he developed, called the Control System

Design Language (CSDL), to support the definition of a design. An environment to interpret the design language and provide the necessary design system supervision and analysis is shown in Figure 1 [Ref. 3].

Figure 1. Flowchart of Design System

1. Design Environment

A CSDL description is written by the designer and is used as input to the design system. The translator decomposes the data from the description into two files: a list of primitives and a timing file. Examples and an explanation of these two files are presented later in this chapter.

The Optimizer module is first to receive these files. This module is tasked to control the overall execution of the system, serve as the input routine, and make a comparison of multiple realizations created by the system and choose the one that meets the criteria as specified by the designer. Following the optimizer is the Functional Mapper. It is the task of this module to ensure that the primitives required by the design are realized in the current realization library. Once the Functional Mapper successfully creates a listing of software titles, it becomes the task of the Timing Analyzer to ensure that all necessary timing constraints are satisfied. With a satisfactory timing analysis complete, the design is considered successful and the final function performed is the actual creation of the software and hardware listings. This process is accomplished by the Formatter. This module extracts from the current realization library all text that

is contained in each primitive in the primitive list and writes this text to the respective software and hardware output files.

CSDL defines functions and their timing constraints using the concept of contingency/task pairs. A contingency is defined as a function of an input variable or variables. The task associated with this contingency is executed only after the contingency is satisfied. Any given design then, must be stated in terms of its contingency/task pairs.

Matelan's Control System Design Language is used as the designer's interface to the overall design process. This language supports the input of a design by problem specification as follows: 1) an identification section, 2) an environment section, 3) a listing of contingency/task pairs, and 4) a procedures section.

The identification section is used as a header and record of when and by whom the design was created. The environment section describes the variables associated with the input and output ports of the device, their electrical characteristics, as well as the variables included in all computations internal to the software implementation. It is analogous to the variable declaration section of high level languages such as FORTRAN or PL/I. The contingency list describes the conditions that must be satisfied prior to the execution of its associated task. This list must also define the timing constraints that must be satisfied when

executing the contingency/task pair. Timing analysis is performed to insure that the time needed to execute a contingency and task falls within the required maximum time allowed by the designer prior to the execution of the next contingency/task pair. Finally, the procedures section contains the routines that make up each contingency/task.

a. Example Problem Description

An example CSDL listing is shown in Figure 2. The identification section is self-explanatory, containing the designers name, the date of file creation and the project name. The environment section contains all the input and output variable names and their bit length (precision). In this example the input variable X and output variable Y are both 16-bit values while the variable DL is a single bit. All of these variables are also identified as being TTL compatible. This section also contains the variable M and it's 16-bits that is used internally to the design. These variable descriptions are contained in the Arithmetic portion of the environment section. The function EXAMPLE that is contained in the contingency list is executed every 10 milliseconds, and when found to be true, the task RELIZE is performed. The final section of this high level description of the problem is the procedures section. It is in this section that the contingency/task pairs are explicitly defined. contingency EXAMPLE is performed by sensing an external

Figure 2. CSDL Design Example

variable INAME. If the value of this variable is equal to one, then the value of EXAMPLE is also set to one. With the value of EXAMPLE equal to one, the contingency is satisfied and the task RELIZE is performed. The task RELIZE is a simple arithmetic expression that senses the value of X, then computes the value of Y using variables, as described in the arithmetic portion of the environment section, as well as any constants required, and latches or otherwise makes the value of the variable Y available at a TTL compatible output port. Had the variable INAME been another value, then EXAMPLE would not be set to one, the contingency therefore would not be satisfied and the task RELIZE would not be performed.

B. CURRENT IMPLEMENTATION

Implementation of Matelan's design system was produced as part of a dissertation by Ross [Ref. 4]. This implementation however, does not support the input translator to the system. A CSDL compiler (translator), designed to be the input module, implemented in Pascal, is under development by Carson [Ref. 5].

The description of the input specification in the previous section is presented for continuity purposes only. In order to relize a design as the system is currently implemented, a number of intermediate files are required.

1. Primitive File

A list of primitives, implemented as the file
PRIMITIVE.DAT, contains a representation of all the required
primitives to realize a given system. It contains each
primitive to be extracted from a realization volume and the
information required to generate the hardware and software
listings. Variable names, data constants, and data size
descriptions are all contained in the primitive listing.
The order of primitives is directly related to the order
required to implement the device. An example of this file
is given in Figure 3. Each line in the primitive file is a
sequential list of the lines to be taken from a realization
library required to fulfill given design requirements.

A system primitive list is always required to initialize pointers, include software heading or assembly language directives, and call the processor primitives required to eventually realize the design. This item is shown in the first group of primitives labeled - t.generated for: system. All of the above requirements are accomplished within the primitive s.main(::). All arguements passed to the primitive are included between the parenthesis and before the first colon. The precisions of any variables passed are contained between the two colons. No information is needed after the second colon, however the second colon is required due to the strict format of Ross' implementation.

Figure 3. Example Primitive List

The first contingency, EXAMPLE, requires a procedure beginning and end, shown by the software primitive s.proc and s.exitproc. The argument passed for this primitive is simply the contingency name. A primitive titled s.eq checks for equivalence between the one-bit variables labeled iname and @cool and if true assigns the 8-bit variable @tl the value of true (=1). The remaining primitives provide constant assignments, establishment of variables, arithmetic routines, and input and output software routines. Hardware primitives are usually called from their software counterparts.

It is from this file that the functional mapper selects a primitive from the realization library that matches not only the title, but also the number of arguments required and the precisions of these arguments.

2. Timing File

A timing file to be used in the analysis of each contingency/task pair must also be generated. This file, IADEFL.DAT, contains the timing constraints imposed by each contingency/task pair. This file is used by the timing analyzer, along with the previously built list of software titles, to determine if the time constraints imposed by the designer are met. Included in this file is the design criteria section, added by Ross to provide a metric by which to determine the optimal realization of a design. The designer may choose one of three criteria to produce a

design realization: 1) first realization that is generated 2) most inexpensive and 3) the realization with the least power consumption. A detailed description of this file is not included here since is not directly concerned with the construction of a realization library. It is mentioned to provide the reader with a better overview of the design environment in which the realization library exists.

III. REALIZATION LIBRARY

Ross' original implementation provided a library of hardware and software primitives using the Intel 8080 microprocessor. This library established the format required to implement subsequent microprocessor libraries. To date, the addition of a Zilog Z-80 library by Smith [Ref. 6], and this thesis, using the Intel 8086, are the only other libraries written. Chapter VI of this paper outlines a method to eliminate the need to write individual assembly code libraries for every microprocessor family.

A. LIBRARY FORMAT

The rigid structure of the realization library format requires the writer to build a library using one of ten possible formats for each line of the library. These formats are:

- 1) primitive title line
- 2) comment line
- 3) calculation line
- 4) attribute line
- 5) call line
- 6) include line
- 7) if line
- 8) begin text line
- 9) endtext line
- 10) text line

Each line of a library begins with a 'v' in column one followed by a four digit line number in columns two through five, and text in columns six through eighty. A line may not extend past column eighty in the current implementation. The first digit of the four digit line number specifies the volume number. If more than 999 lines are needed in a library or more than nine volumes are written, alphabetic characters can be used.

The first line of the library, line number vx000 (where the x is the volume number), identifies the microprocessor family (intel 8086 cpu), the clock period, any additional delays in accessing memory, and a monitor constant all used in the timing analysis to determine if a particular design is realizable. Each of these attributes are separated by colons (see the first line of the realization library, Appendix C). Following this line is the library index, which is a copy of every primitive title line contained in the library. Line numbers in the index are not consecutive, but are the actual line numbers of the primitive title lines' location in the body of the library. However, a counter tracks each line listed in the index so the first primitive title line in the body of the library contains its actual line location from the beginning of the library, including the index listing. The index of primitives is followed by an '.end index' line starting in column seven.

1. Primitive Title Line

Title lines define either hardware or software primitive types. A decomposition of a hardware and software title line are shown in Figures 4 and 5, respectively. The hardware title line starts with an 'h' in column 6, a period in column 7, and the primitive title in column 8 through 17. If the title is less than 10 characters in length, then blanks are inserted through column 17. Column 18 contains a left parenthesis followed by the parameters of the primitive. These parameters are listed in three variable length fields separated by colons. If any of these fields are empty, the colons must still appear. The first field specified the dummy argument names, followed by a colon, with the selection criteria in the second field. Argument names can be up to six characters in length and are separated by commas. The arguments must appear in the same order as the actual arguments in the primitive calls.

The selection criteria, in the second field, contains the minimum and maximum size, in terms of bit count or precision, of each argument. Each of these values are separated by commas. These values are used by the functional mapper to determine if the primitive realization meets the requirements of the primitive being invoked. This field is also followed by a colon.

The third field contains the attributes of the realization. For a hardware primitive, these attributes are

Figure 4. Example Hardware Primitive Title Line

Figure 5. Example Software Primitive Title Line

(in order, separated by commas): 1) latency of the device (delay in accessing), 2) amount of power required by the electronic components contained in the primitive (in milliwatts), and 3) the number of chips contained in the primitive. For a software primitive, these three attributes are (again in order, separated by commas): 1) number of 8-bit bytes of storage required, 2) the number of clock cycles required to execute the primitive, and 3) the number of references to external memory made during the primitive.

Both hardware and software primitives use the next four attributes as a flag to indicate whether any calculation ('calc') or include ('incl') lines are contained in the primitive, and the line numbers of the first and last line of the primitive within the body of the library. If no 'calc' or 'incl' lines are contained in the primitive, a value of zero is given to these attributes. A primitive that contains a 'calc' or 'incl' line has a value inserted into this location that corresponds to the offset from the first line of the primitive to the line where a 'calc' or 'incl' does occur. If any of these attribute values depend on formal parameters passed by the calling primitive line, the attribute is given a negative sign in the title line. The offset to an attribute ('attr') line which calculates the actual value of the corresponding attribute in the absolute value of this negative attribute in the title line.

2. Comment Line

Each comment line begins in column 6 with 'com'.

Columns 9 through 80 can be any desired text, numerals, or special characters. This line is ignored by the system and is therefore not written to any output file.

3. Calculation Line

Calculation or 'calc' lines are used in library primitives to manipulate system global variables. This line begins with 'calc' in columns 6 through 9. The list of available system globals and the definition of each is contained in Appendix B. This global list is a combination of Ross' original implementation and Pollock's [Ref. 7] additions for the Intel 8080 cpu, and the additions provided by this paper. This universal globals list is generated to provide the design environment with the ability to select between microprocessor families in order to selected the appropriate realization to meet timing and design criteria without the need for a separate globals list for each library. The 'calc' lines assign values to the global variables during the generation of the design. Calculations are performed using mathematic expressions with global names and dummy parameters as variables. Arithmetic operators available are +, -, *, -, and ** and any number of pairs of left and right parenthesis to force the order of execution of operators. The operators are interpreted in the same way as they would be in Fortran.

4. Attribute Line

Similar to the 'calc' line, attribute lines begin with 'attr' in columns 6 through 9 and are used to calculate the value of the attributes contained in the first three parameters of the third field of the primitive title line. For example, depending on the value of a certain global variable, a primitive may or may not add a new hardware component to the hardware realization. This means that a check would be required within the primitive to determine whether to include a component or not. The title line would show a chip count of zero, but following a check of a global for a certain value signifying the need for the addition of the component, the chip count would be increased by one using the 'attr' line (see Figure 6).

5. Call Line

This line is used to provide control within the library to invoke other primitives. As with other line items, this line begins with 'call' in columns 6 through 9. Prudent use of the 'call' line results in the reduction in the overall size of the library. A 'called' primitive's text is added to the output listing at the place where it is called.

6. Include Line

An include line is similar to the 'call' line with the difference being the included primitive text is placed at the end of the output listing after all of the other

Primitive with Flag

(Attributes computed within the primitive)

Equivalent Primitive with Attributes in Title Line

Figure 6. Example Attribute Line Entry

primitives in the Formatter input primitive list are finished. This line begins with 'incl' in columns 6 through 9. The 'incl' line is used mainly to add hardware to the hardware output listing during the generation of the software output. For example, the addition of a hardware I/O port during the addition of the software text that supports the checking of information at that port address.

Both the 'incl' and 'call' lines must contain the actual arguments and selection criteria fields, if needed.

Spacing requirements are the same as for the primitive title line and must be observed. Arguments must start in column 19 preceded by a left parenthesis in column 18 and must be separated by commas and followed by a colon. Another colon must follow the selection criteria field, if present, and the line must end with a right parenthesis.

7. If Line

Conditional branching is accomplished within the library by use of the 'if' line. This line begins with 'if' in columns 6 and 7 followed by a mathematic expression, a relational operator, .ne., .gt., .ge., .lt., or .le. (meanings as in Fortran), another mathematic expression, and a skip instruction to by-pass any number of lines forward or backward from the 'if' line within a primitive. The format for this statement is:

if <math exp> <rel op> <math op> skip <# of lines>

If a backward skip is required a negative value is used for the "# of lines" argument. A skip backwards includes the 'if' line executing the branch and the line to be executed upon completion of the skip. This process is shown in Figure 7. An unconditional branch can be invoked by using the skip portion of an 'if' line.

8. Begin Text Line

This line precedes the actual lines of text that appear in the output listing and in combination with the 'endtext' line brackets the text of the primitive. The line begins with 'begin htext' for a hardware primitive, and 'begin stext' for a software primitive, in columns 6 through 16. No other characters appear on a begin text line.

9. Endtext Line

This line begins with 'endtext' in columns 6 through 12, for both hardware and software primitives, and in combination with 'begin text' marks the end of a text listing that is destined for an output file. Any number of 'begin text' and 'endtext' lines may appear in a primitive, but they must be used in pairs.

10. Text Line

A text line is free-form and allows the library writer to format lines of text between 'begin text' and 'endtext' in any way that will later be compatible as hardware and software output listings. These lines contain

Backward Number of Lines Skipped \sim \sim Forward 0 \sim \sim if mem .ge. ramptr skip 4 -calc mem = mem - 10calc cnt = cnt + 1 begin stext incl h.ram skip -5 Line # 9 4 2

Figure 7. Example If Line Entry

volume and line numbers, therefore the only restriction is to limit the text to columns 6 through 80. All text contained in text lines will be copied to the output listing exactly as written with two exceptions. Variables enclosed in pound signs (#) are interpreted as a call to a system procedure or function. The corresponding procedure will be implemented to generate character strings for the output listing. An example of this is the use of the #IDSEC# function in the primitive s.heading of Appendix C. This copies the lines of the identification table from the input file to the output listing. The other exception is the use of dummy arguments enclosed in brackets '<' and '>'. Each time a dummy argument is encountered in a text line enclosed in brackets, the current value of that argument is written to the output listing in the location specified in the text line.

IV. 8086 LIBRARY IMPLEMENTATION

The use of the Intel 8086 16-bit microprocessor is a logical extension of the currently available realization libraries to CSDL. Due to the similarities of the 8080 and Z-80 microprocessor architecture and instruction sets, a good comparison of execution speeds of a given design is easily done. In some cases, for example, a control system realization may not be possible with the slower 8080 cpu, but may easily be implemented by the Z-80 or 8086. The variables of cost and power consumption must also be taken into account to make a final decision as to the 'best' realization to be used (recall that these factors are part of the design criteria section of CSDL).

A. MEMORY ORGANIZATION

Figure 8 shows the standard memory map of the 8086.

Memory organization used in the 8086 realization library is opposite from the previous two libraries. Whereas the 8080 and Z-80 libraries build the ROM (instruction) area from low to high memory locations and RAM (data and stack) area from high to low memory locations, the 8086 builds RAM from low to high with ROM stepping from high to low in 64K byte steps. Stack RAM is isolated from data RAM by use of the segment registers, discussed later in this chapter.

Figure 8. Standard 8086 Memory Organization

Realization library memory organization is illustrated in Figure 9. Stack memory occupies the lowest 1K of RAM followed by the data RAM which is allowed to increase in size up to the lower limit of the ROM area. This configuration chooses to take advantage of the instruction pointer (IP) being set to address FFFFOH upon microprocessor reset and the default value of the code segment register set to the highest 64K byte block of memory. Instructions are written into ROM by stepping to the lowest address of a 64K byte block and then incrementing addresses for each succeeding instruction. At the highest address location in any 64K byte block, a JUMP instruction is inserted to jump to the lowest address of the next lower 64K byte block of memory (see Figure 10). By keeping instructions in high memory, there is no overhead associated with manipulating segment register values that would be required to embed instructions in the middle of what would otherwise be data or stack memory addresses. Therefore, instruction ROM area remains in the higher memory locations. However, this method only allows for a code section 65516 bytes in length in this library's implementation. This is due to the inability of the design system to check for the current ROM pointer value during software file generation and evaluate the 'stuffing' of a jump instruction in the last three bytes of the current 64K byte memory block. A method to evaluate

Figure 9. Memory Organization in the 8086 Library

Figure 10. Insertion of JUMP Instructions

a primitive's assembly code line by line is necessary to execute this procedure, since a primitive may exceed a 64K byte memory boundary partially through that primitive's code. An alternative to this method would be to allow the system to delay the binding of ROM addresses until the entire instruction code has been generated. The appropriate number of 64K blocks of memory could then be generated for the hardware output listing. Once this is done, the address of the lowest block of memory may be inserted into the JUMP instruction located at FFFF0H using the system equates (e.g. sys14) found at the beginning of the assembly heading. This would then allow an uninterrupted, linear address space for use by the IP without the associated overhead of adding jump instructions at the high address of each 64K byte memory block. A third alternative would be to arbitrarily partition memory into two 512K byte segments, one for code and one for data/stack.

With program code in high memory, the stack and data RAM sections are put into the lower addresses. A stack area of 1K is established in the first 1K of memory. Immediately following the stack area is the data area. This area is allowed to grow to any size, up to the ROM area. For very large programs where data RAM and instruction ROM addresses approach each other, a scheme must be incorporated to ensure that neither of these areas will occupy a portion of the

same 16K byte block of memory. Figure 11 shows how this conflict is resolved. Current implementation does not consider this possible error condition.

1. Segment Registers

Addressing the one megabyte of memory available to an 8086-based system does not follow the standard microprocessor addressing convention. A 20-bit address bus is required to support the entire address space. Register structure within the 8086 is only 16-bits wide. To accomplish the construction of a 20-bit address, a second summer is used in conjunction with one of four segment registers. These segment registers define a base address within a 64K byte block of memory which allow code, data, and stack values to be separated in physical memory. capability exists to fully or partially overlap segments within the physical memory space by storing the appropriate values in the respective segment registers. As is shown in Figure 9, the stack and data 64K byte segments overlap with the exception of the lowest 1K of memory. An "extra" segment can also be defined for whatever purpose the programmer deems necessary. This extra segment is not used in the construction of this library. Figure 12 illustrates how segment registers define base addresses. Figure 13 shows how these registers are used for computing an address. A 16-bit address in the IP, called the logical address, is

Figure 11. Overlapping of ROM and RAM Areas

Figure 12. Definition of Base Addresses by Segment Registers

Figure 13. Constucting a 20-Bit Physical Address

added to the value contained in one of the segment registers, the base address. Prior to the addition, the base address is multiplied by sixteen, which effectively performs four left shifts and 'stuffs' zeros in the least significant nibble. The result of this addition produces a 20-bit real address that is subsequently placed on the address bus. On microprocessor reset, default values for the segment registers are loaded, but may be changed at any time by the program or upon assembly if the code, data, or stack regions extend beyond their respective 64K byte boundaries.

Changing the values of these registers within the primitives of this library is not done, with the exception of stack and data segment initialization. As program size increases, there exists a requirement to change the values in the segment registers as code or data cross 64K byte boundaries. The process of determining when to load a new base address into a segment register is transparent to the programmer, since this task is accomplished by the assembler.

2. Input/Output Memory

Input/Output memory is implemented in the 8086 as a separate 64K byte block of memory located in the lowest address space. In this implementation, I/O memory is restricted to the lowest lK byte of memory. Although

arbitrarily chosen, this amount of I/O should accommodate even the most I/O oriented design. Any requirement to increase I/O memory can easily be accomplished by substituting a new base address for data RAM, thus allowing the stack to grow into the current data address space.

3. Interrupt Handling Considerations

Current implementation of CSDL does not support an interrupt driven, real-time controller. Therefore, the interrupt (INTR) and non-maskable interrupt (NMI) pins are tied to ground. Memory space that is normally reserved for interrupt handling in low memory of the 8086 is ignored and has been designated as the lower quarter of stack memory. If further research allows for interrupts in controller system generation, all that is required to alter the current memory map convention is to shift both the stack base address and the data base address values to an address area above the highest interrupt address. Without changing the data segment, a configuration allowing all 256 interrupts and a stack size of 768 bytes could be implemented by only shifting the stack base address to 256D.

B. OPERATING SYSTEM CONSIDERATIONS

The system monitor constructed from library primitives forms the operating system of the design realization (more on the monitor later). No outside intervention in the operation of controllers produced by this CAD system is

anticipated. Therefore, all memory is available for use by the code, data, and stack only.

C. HARDWARE DESCRIPTION

A large memory space combined with a high speed microprocessor makes even the simplest of hardware configurations generated from this library chip intensive. The composition of the library is based on individual IC's and their eventual integration onto a printed circuit or wire-wrap board. This follows the convention of the original 8080 library. It becomes possible then, to make a direct comparison between the two libraries when attempting to make a design criteria check. This differs from the prototyping scheme used by Smith in the generation of the Z-80 library.

1. 8086 Microprocessor and Support Chips

To allow for faster performance at the hardware level, the Intel 8086-2 8MHz microprocessor is used.

Although a faster version, the 8086-1, is available which runs at 10MHz, the choice to remain at 8MHz is based on two requirements. First, and foremost, is memory compatibility. The option to obtain memory devices from other manufacturers was available, but for power requirements and overall system integrity, the use of Intel produced memory chips was made (discussion of memory follows later in this chapter).

Secondly, the choice to proceed with the 8MHz version is

cost. In the long term, however, with the cost of most popular integrated circuitry decreasing, this point may be of little consequence.

Two modes of operation are available with the 8086 cpu. These are the minimum and maximum modes. The minimum mode is used for single processor, minimum chip count applications. The maximum mode allows multiprocessing and attached co-processor systems. All that is required to configure the processor into one or the other of these modes is to tie the MN/MX pin to + 5 volts for minimum mode, or tie the same pin to ground for maximum mode. Depending on the mode chosen, the 8086 will issue all control signals (minimum mode) directly to memory and peripheral devices, or issue status signals to a bus controller (maximum mode) which, in turn, are decoded into the appropriate control signals. The status signals issued by the maximum mode 8086 provide the information necessary for a local bus. local bus is used to provide the needed information and control to attached co-processors in a multiprocessing environment. Figure 14 illustrates the 8086 configured in the maximum mode. The maximum mode is the mode chosen to be implemented in this library. This is done to allow the use of an attached numeric data processor (NDP), the 8087. implement the 8087 NDP, current procedure requires the system designer to change the value of the flt flag in the GLOBALS.DAT file from a zero (0) to a one (1). This flag,

Figure 14. 8086 in Maximum Mode

in turn, calls the 8086 CPU primitive that is configured for exchanging request/grant and queue status signals from/to the 8087.

Timing for the system is provided by an Intel 8284 clock generator, running at 8MHz. This device requires an external 3-times, or 24MHz, crystal for proper operation. In case the option to use the 8087 NDP is chosen, the clock generator must provide a 5MHz frequency using a 15MHz crystal. This is provided for, within the structure of the hardware primitive.

To ensure the proper power levels are available at the data ports of memory, two Intel 8286 octal bus transceivers are used as line drivers. Each transceiver provides 2-way drive for the upper and lower bytes of the 16-bit data word.

Due to the multiplexing of addresses and data on the external pins of the 8086, a requirement exists to latch the address to some other device to allow the data to be made available at some of these same pins. Three Intel 8282 octal latches provide this latching mechanism.

2. Memory and Memory Support Chips

Two types of memory are required to support any system generated. First is some form of ROM that will subsequently receive the instruction code from the software listing. Second is the RAM to be used for data storage and as stack memory as well as RAM for the I/O memory space.

The ROM used in this library are two Intel 27128 16K by 8-bit ultra-violet EPROM's, one for the upper byte, one for the lower byte for every 16K block of memory needed for the system.

Data and stack RAM use sixteen Intel 2167-10 16K by

1-bit static RAM, again, for every 16K block of memory

required. This particular memory device is selected to

meet the memory access speed requirements of an 8MHz CPU

without the necessity for the insertion of wait states.

Although the instruction queue in the bus interface unit of

the 8086 contains prefetched instructions and data, thereby

eliminating most of the requirements to insert wait states,

a fast memory has been chosen to meet any immediate memory

access requirement (e.g. those imposed by jumps or branches).

No other memory options are available, even if the slower

5MHz clock is selected for use with the 8087 NDP.

Input/Output RAM use four Intel 2142 1K by 4-bit static RAM as direct I/O addresses that are available in the 8086.

All ROM and RAM chips are supported by AMD 74LS244 octal three-state buffers as address line drivers integrated into the design to ensure that no single address line has a fan-out of more than 15.

Since 16K blocks of ROM, and data and stack RAM are used, only address lines 1 through 14 (Al - Al4), are needed to select any one byte or word. The full memory is made up

of 32 of these 16K blocks. Therefore, a memory decoding scheme has been implemented to select 1-of-32 16K memory banks. Eight Intel 8205 1-of-8 binary decoders are used in banks of four to select the even and odd byte of the address. The decoders are all driven by address lines Al5 through Al9 and address zero (A0) for the odd address byte, BHE for the even address byte, with both A0 and BHE active for an aligned 16-bit word (see Figure 15).

3. 8087 Numeric Data Processor

When used, the 8087 NDP extends the register and instruction sets of the 8086 CPU for the purpose of high-speed floating point operations. The hardware implementation of the 8087 NDP is the standard local bus arrangement as shown in Figure 16.

4. Other Hardware Support

Hardware support to meet various possible design requirements is included in the library. Many of the discrete components were taken from Ross' and Pollock's original works and are included in the 8086 library for continuity. A complete list and description of the components are contained in Appendix A.

D. SOFTWARE DESCRIPTION

A listing of the software primitives and their descriptions are contained in Appendix A. Items of particular interest are discussed in more detail in this section.

Figure 15. Decoding Memory Banks

Local Bus Signals

Figure 16. 8087 Numeric Data Processor on Local Bus

1. Monitor Section

The control or monitor section of the software primitive list follows the convention found in the 8080 library. As shown in Figure 17, the monitor consists of a pointer, a table and a section used to test each contingency prior to the execution of its associated task.

A pointer is used to direct the checking of every contingency described in the system's input file. Each contingency is listed in the monitor table in order of actual execution. The pointer's value is the address associated with the current instruction being executed in the monitor table. After each contingency/task check and possible task execution, the value of the pointer is increased to point to the next address in the monitor table. Once the monitor table has been traversed completely, the supervisor is executed, thereby resetting the value of the pointer to the address of the first instruction in the monitor table. This process continues indefinitely until a fatal error occurs or power is turned off to the controller.

2. Calculation Section

Most arithmetic primitives are straight-forward applications of the available 8086 mneumonics. Unlike this libraries predecessor's, where multiply and divide routines contained many lines of code, the 8086 has nmemonics that made these otherwise rigoruos tasks, a simple, single line of code using the various types of the multiply (MUL) and divide (DIV) instructions.

```

Figure 17. Example Monitor Section

a. Arithmetic

All simple arithmetic operations, add, subtract, multiply, and divide, are implemented for 8- and 16-bit integer arguments.

Variations in Simple Arithmetic Routines. Along with the simple arithmetic operations, several error checking primitives are available. These are currently used by the system designer as line items in the intermediate primitive list. Once listed in the intermediate file, that specific primitive will be taken from the realization library and used in the software output listing provided that all timing requirements are met. In the future, the designer that uses this system will be queried by the input program whether to incorporate error checking in any or all routines. In all cases, primitives that contain error checking require more memory and take longer to execute than those which have no checking. Many circumstances that arise in the use of a fixed length word or byte as the storage. size, provide more than enough bits to cover the range of values of possible arguments. If the designer believes that, for example, an 8-bit add would not cover the possible values of the addends, and the actual result is an important value, as opposed to selecting just the most significant byte for example, then the 16-bit addition without error checking could be used without a penalty of memory used or execution time to implement the addition. An important

point here is that error checking and subsequent correcting, in most cases, substitutes the largest value, either negative or positive depending on whether overflow or underflow occurred, as the value of the result of the arithmetic operation.

Multiplication operations provide several options for the designer's use. These options include 8- by 8-bit or 16- by 16-bit multiplies with options to return an unchecked 8- or 16-bit result, respectively. Also 8- by 8-bit or 16- by 16-bit multiplies, returning a 16- or 32-bit result. Another option is the multiplication of the same size values and returning an unchecked upper or lower byte or word as the result. Appendix A contains a listing of the software primitives as implemented in the realization library of Appendix C.

b. Floating Point

All floating point operations use the Intel short real format. This format is composed of 32-bits with the sign of the mantissa in the most significant bit, followed by an 8-bit signed exponent, and finally followed by a 23 bit normalized mantissa, where the most significant bit of the mantissa is implied to always contain a one. The range available in this format is 8.43E-37 to 3.37E38 [Ref. 8]. To be used as data within a floating point primitive, the library assumes that the 32-bits of the floating point variable passed from the primitive list will be in the

proper double word format, as described above, with the most significant word in the lower storage address and the least significant word in the next higher address. For compatibility with the 8080 library, this data is labeled in byte format, from MSB to LSB, as exponent (exp), high mantissa (hmant), middle mantissa (mmant), and low mantissa (lmant). This method of storing a floating point variable is also compatible for use with the 8087 NDP. Figure 18 illustrates the composition of a floating point variable using this format.

Current implementation of floating point arithmetic makes use of the 8087 NDP only. No stand alone software for floating point manipulations are included in the library. However, provisions have been made to incorporate software-only floating point operation by writing primitives to pack and unpack floating point variables into and out of the short real format for ease of manipulation within the arithmetic routines. The unpack primitive separates the mantissa sign bit, the exponent, and the mantissa into individual bytes, words or double words and is then stored into a designated scratchpad area in RAM. Upon completion of a floating point operation, the values are packed into the proper format prior to being stored as the result. The current implementation must pack and unpack variables each time they are

Labels given to each byte of a floating point variable or constant (provides compatibility between 8080 and 8086 libraries)

Figure 18. Floating Point Variable Format

used, since there is no method to keep track of variables that have been previously used during the execution of a systems design.

The choice for using the 8087 NDP for all floating point operations, as shown in Figure 19 [Ref. 9], is speed. Without the 8087, a single precision floating point addition would require about 6.2 milliseconds to complete in an optimized environment. This takes into account two single precision loads, one floating point addition, and one single precision store. This is in comparison to 53 microseconds that an 8087 NDP would require to accomplish the same operation. This is a better than a 100 times improvement over the 8086 software floating point addition. In many cases, for a real-time controller design, 6.2 milliseconds will not satisfy speed requirements for multiple floating point computations.

Prior to any 8087 floating point operation, the NDP must be initialized by the loading of a control word. The control word provides programming options for allowing or disallowing the recognition of interrupts, precision specification (data type selection), rounding control, infinity control and exception handling options. The control word used in the initialization of the 8087 NDP in the library are selected as follows:

INSTRUCTION	APPROXIMATE EXECUTION (MICROSECONDS)	
	8087	8086
ADD SIGN-MAGNITUDE	14	1600
SUBTRACT SIGN-MAGNITUDE	18	1600
MULTIPLY (SINGLE PRECISION)	19	1600
MULTIPLY (DOUBLE PRECISION)	27	2100
DIVIDE	39	3200
COMPARE	9	1300
LOAD (DOUBLE PRECISION)	10	1700
STORE (DOUBLE PRECISION)	21	1200
SQUARE ROOT	36	19600
TANGENT	90	13000
EXPONENTIATION	100	17100

Figure 19. Speed Comparison Between 8087 NDP and 8086

- 1) interrupts disabled
- 2) short real data type (24 bits of precision)
- 3) round to nearest value or even
- 4) projective infinity control

Items 1 through 3 are self explanatory.

Item 4, projective infinity control, provides the control necessary to close the system of numbers in the 8087.

Although affine closure provides more information than projective, there is a greater chance for misinformation by using the affine closure mode if, for example, the reciprocal of plus or minus zero is computed. Figure 20 shows that the result of this computation would give two different results for the same values in the operation.

The projective mode never returns misinformation and is therefore the suggested mode for use when the values of an operation are not known in advance. [Ref. 10]

Due to the serial nature of the processing environment of CSDL and the 8086/8087 structure within the environment, optimal use of the processing group is sacrificed for the stand-alone speed capabilities of the 8087. As shown in Figure 2la [Ref. 11], the 8086 in a co-processing environment with the 8087 is afforded the ability to continue fetching and executing its instruction stream while the 8087 is performing a more involved floating point operation. Once the 8087 has completed its task, it interrupts the 8086 just long enough to store the result of its previous computation. In this library implementation,

Projective Closure

Projective closure provides a completely closed set of numbers, thereby never providing misinformation.

Affine Closure

More information is available with Affine closure but is not recommended when the values of variables are not always known

Figure 20. Projective versus Affine Closure

as the environment of system design forces serial calculations, the 8086 is immediately dependent on the outcome of the 8087's current calculation. This requires the 8086 to enter an unproductive idle state as shown in Figure 21b. The overall calculation speed of this system is increased, however, at the expense of adding 8087 NDP hardware for floating point operations. A tradeoff in overall system speed must be made when the 8087 NDP is used, since the 8086 CPU must be slowed to a 5MHz rate with the addition of the 8087 hardware.

(2) Emulation of the 8087 Numeric Data Processor. If speed is unimportant in a particular realization which contains floating point operations, and the decision not to use the 8087 NDP is made, an alternative to creating complete software-only primitives for floating point calculations is the use of the 8087 emulation package that provides the software equivalent of the 8087. With this package installed, no difference exists between a routine that will run on the 8087 or 8086 emulation of the NDP. The decision to use the 8087 hardware is made at link time, with no further re-assembly required to produce the proper 8086 code [Ref. 12]. All that is required, in this case, would be to substitute the values for execution cycles in the software primitives of the library to ensure an accurate timing analysis is performed prior to the generation of the system design listings.

Figure 21a. Normal Co-processing Environment

Figure 21b. Co-processing Environment in 8086 Library

Figure 21. Use of ESC Codes in a Co-processing Environment

3. Logical Functions

Included in this library is a complete set of software primitives to perform logical operations. These include 8- and 16-bit and, or, not, xor, eq, lt, le, gt, ge, and ne. All of these primitives are compatible with those in the 8080 and Z-80 libraries.

4. Other Software Functions

Among the remaining primitives contained in this library are program control and input/output control.

Program control includes those primitives required to establish storage areas for constants, set up variable storage areas, define line labels to be used for conditional jumps, jump on true or false, as well as primitives to set up for-loops, while-do loops, and establish and call procedures. A fixed-length delay primitive allows the designer to specify a delay, to wait for an input for example, in increments of 5 microseconds for both the 8MHz and 5MHz design versions.

Input/Output control provides for 8- or 16-bit input/output bytes or words. The software primitives are taken from the original 8080 library.

V. TESTING OF SOFTWARE PRIMITIVES

A. PRIMITIVE TESTING VEHICLE

Software primitives for this library were developed and tested on the Naval Postgraduate School Mathematics

Department's North Star Computer, Inc., "Horizon" computer system, augmented with an Octagon Computer System's "Octagon Board 8/16" plug in processor board. This S-100 board gives to the normally Zilog Z-80 based "Horizon" an 8086/8087 processor capability. The 8087 Numeric Data Processor is not currently installed on the 8/16 board. Those primitives that make use of the 8087 NDP are, therefore, not operationally tested. Primitives that use 8087 code are taken in part from examples given in the book, 8087 by Richard Statz [Ref. 13]. Although these 8087 primitives may not function properly, if implemented, they are included as a starting point for future investigation.

In conjunction with the use of the "Horizon" computer, the testing environment operated under CP/M-86. All programs writtenfor verification purposes to be used as primitives in this library were assembled using ASM-86. It should be noted that other assemblers may have directives that do not equate to those directives used in this library, and any assembly errors may be due to the incompatability of these directives.

B. TESTING OF CONTROL LOGIC

All primitives that contain 'if' lines, and therefore have conditional branches, have been tested for all possible branches. For example, the addition of an 8087 NDP requires that the clock period attribute be changed from 0.125 microseconds to 0.2 microseconds, the crystal used with the 8284 clock generator be changed from 24MHz to 15MHz, and all the associated changes be made to accommodate the slower overall system speed. In this example, the FLT global variable is used as a flag to signify the addition of the 8087.

VI. RECOMMENDATIONS AND CONCLUSIONS

A. RECOMMENDATIONS

1. Universal High-Level Language Realization Library

A large scale reproduction of basic software primitives required to create another realization library is far too labor intensive to be performed for each new microprocessor family. The following paragraphs explain how this section of library creation may be avoided.

A single high-level language library created by developing software primitives, would provide instant compatibility between different microprocessor families. Once a high-level language library is written, the use of a cross compiler/assembler could be used to construct the actual library used by the timing analyzer and formatter. Cross compilers are currently available to convert C language programs to any number of target microprocessor machine code programs [Ref. 14]. The hardware portion of the new library would still be constructed component by component. After the cross compiler produces an assembly language/machine code file for timing analysis, the appropriate hardware primitives are appended to the assembly language file. Another volume of timing and size primitives, constructed to match the microprocessor, would provide the number of cycles and bytes required to realize a given

design. This timing/size companion volume would simply be a rewritten version of the new microprocessor's index of mnemonics, usually provided in the processor programming guide. An example of this process is shown in Figure 22.

2. Hardware Wiring Diagrams

The current method to implement hardware components is left to the realization library author. Although pin-out descriptions are simple, several areas in the hardware text section is free-form. With the potential to diagram the hardware realization to a high resolution graphics terminal, a more structured format in the hardware section is suggested.

B. CONCLUSIONS

The integration of the Intel 8086 microprocessor realization library into the overall design capabilities of CSDL offers comparable primitives to that of the original works by Ross and Pollock. A universal globals file (globals.dat), as constructed in this paper, must be maintained to allow the design criteria section of CSDL to migrate from microprocessor to microprocessor library to generate the desired system by meeting the design specifications. This option was not maintained by Smith in his prototyping scheme for the Z-80 realization library, and therefore, his specialized globals are not included in the universal globals file. Libraries constructed for use by this design system should continue to be produced in order

Software Library Implementation Universal High Level Language 22. Figure

to provide a wide range of processor families from which to choose. With the eventual integration of a "user friendly" input method, CSDL will provide an advanced environment in which to design and implement real-time microprocessor-based controllers.

APPENDIX A

DEFINITIONS OF PRIMITIVES

List of hardware and software primitive functions. The primitive definitions preceded by an (*) are from the 8080 library that are also used in the 8086 library.

h.adc.	×	Defines	an	8-bit	analog	to	digital
		converte	er				

h.capac-cer " Defines any value ceramic capacitor.

h.clckctrs * Defines a 16-bit TTL counter for a free running clock.

h.conn-al * Defines dip socket used as an analog connector.

h.dac * Defines a 8-bit digital to analog converter.

h.diode-sw * Defines a silicon switching diode.

h.drvr Primitive to implement address line drivers as more 16K banks of memory are added to the hardware realization.

h.eprom

Defines the pin-out of an Intel 27128 128k ultra-violet erasable programmable read-only memory.

h.ffjk * Defines a TTL flip-flop.

h.follower * Defines a voltage follower.

h.herr

Performs a simple check to determine if
ROM space overflows into RAM space and
prints a warning message if an overflow
occurs.

h.invert * Defines a TTL inverter. Defines the pin-out of an Intel 2142 4k h.ioram static RAM for input/output memory. h.issuecond * Defines an 8- or 16-bit condition-type output hardware. * Defines a single bit output. h.issuesepcd * Defines event-type output hardware. h.issuevent Calculates the required read-only and h.memory read-write(ram) memory chips required to implement the current design. It also assigns the chip select line numbers generated by the address decoder hardware primitive that is contained in the processing unit primitive, h.processor. h.nand2 * Defines a 2 input discrete nand gate. h.nand3 * Defines a 3 input discrete nand gate. h.nand4 * Defines a 4 input discrete nand gate. * Defines an 8 input discrete nand gate. h.nand8 Defines the pin-out of the Intel 8087 h.ndp Numeric Data-Processor for high speed floating-point calculations. Defines the pin-out of the Intel 8086-2 h.nprocessor 8MHz microprocessor for use with an Intel 8087 Numeric Data Processor. h.oneshotl * Defines a TTL edge triggered, retriggerable one shot.

* Defines operational amplifier hardware. h.opamp

h.opisol2 * Defines a slow photo darlington optical isolator.

h.optoisol * Defines optically isolated logic device.

h.oscxtal * Defines a modular crystal oscillator.

h.peripdrivr * Defines peripheral driver hardware.

h.processor

Defines the pin-out of the Intel 8086-2 8MHz microprocessor for use without any attached coprocessor.

h.ram

Defines the pin-out of the Intel 2167 16k static read/write(ram) memory chip.

h.relaydpdt

* Defines a double-pole double-throw relay.

h.resmfqtrwt

* Defines 1/4 watt metal film 1% resistor.

h.rpack-18b

* Defines 8 resistor, 180 ohm each, resistor package in a 16 pin dip.

h.rs232conn

* Defines rs-232c input/output connection.

h.rs232rx

* Defines an rs-232c receiver.

h.rs232tx

* Defines an rs-232c transmitter.

h.sensecond

* Defines 8- or 16-bit condition-type input hardware.

h.sensepcond

* Primitive to define a single bit input device.

h.sensevent

* Primitive to define an event-type input hardware.

h.striginvrt

* Defines a TTL schmidt trigger inverter.

h.support

Defines the support IC's required for use with both variations of the 8086 processor. This includes the following chips:

1. Intel 8284 Clock Generator and driver.

2. Intel 8286 Bus Transceiver.

3. Intel 8288 Bus Controller.

4. Intel 8282 Octal Latch.

5. Intel 8205 1-of-8 Decoder.

h.trimpot

* Defines a variable resistor of (r) ohms with a 1/2 watt trimpot.

h.uart

* Primitive to define a UART.

s.8087cw

Routine to load the 8087 control word prior to the first 8087 NDP operation. The control word specifies:

1. Intel short form for floating point data representation.

- 2. Rounding to nearest or even value.
- 3. Projective infinity control.
- s.add Primitive to add two 8- or 16-bit integer numbers.
- s.addck

 Primitive to add two 8- or 16- bit integer numbers with overflow and underflow checks. If an overflow error exists the largest positive number is stored as the result. On an underflow condition, the largest negative number is then stored as the result.
- s.anain * Primitive to define a processor-controlled analog input.
- s.analogin * Primitive to define an analog input condition.
- s.anaout * Primitive to define an analog output channel.
- s.and Primitive to perform a logical 'and' of two 8- or 16- bit numbers.
- s.assign * Primitive to assign an 8- or 16-bit value of one variable to another variable.
- s.assigncons * Primitive to assign an 8- or 16-bit constant to a variable.
- s.clock * Primitive to define a free running time clock.
- s.cons

 Primitive to define a data constant to be used at program assembly time.
- s.div Divide routine for 8- or 16-bit unsigned division.
- s.end Defines the end of the output assembly language listing.
- s.eq Primitive to determine if two 8- to 16- bit integers are equal.
- s.eventmark * Primitive to establish interrupt handler for event.

Primitive to define dummy function for s.every every-period statement. Closes a procedure and resets the associated s.exitproc contingency. Routine to perform floating point addition. s.fadd Routine to assign the value of one floating s.fassign point variable to another floating point variable. Routine to define storage for a floating s.fcons point constant in short real form. s.fdiv Routine to perform non-numeric data processor floating point divide. s.fix Routine to convert a floating point value to an integer value. Routine to delay a fixed period of time in s.fixedwait 5 microsecond increments for an 8MHz clock. s.fixedwait5 Routine to delay a fixed period of time in 5 microsecond increments for a 5MHz clock. Routine to convert an integer value into s.float a short real format floating point value. s.fmul Routine to perform non-numeric data processor floating point multiply. Defines the start of a constant bounds loop. s.forcons s.forend Defines the end of a constant bounds loop. s.fpack Routine to pack an unpacked floating point result of a non-numeric data processor floating point operation. This puts the result of a non-numeric data processor floating point operation back into memory in short real form. (See s.funpack). s.fsub Routine to perform a non-numeric data processor floating point subtraction.

s.funpack

Routine to unpack a floating point argument prior to a non-numeric data processor floating point operation. The argument is stored in short real form prior to unpacking. (See s.fpack).

s.fvarset

Primitive to establish a scratch-pad in memory to handle non-numeric data processor floating point operations.

s.ge

Determines if argumentl is greater than or equal to argument2 for 8- or 16-bit numbers.

s.gt

Determines if argumentl is greater than argument2 for 8- to 16-bit numbers.

s.heading

Primitive to define assembly language software heading.

s.imull6

Primitive to multiply two 16-bit signed integer numbers without overflow checking and returns a 16-bit result.

s.imul8

Primitive to multiply two 8-bit signed integer numbers without overflow checking and returns an 8-bit result.

s.imulex16

Primitive to multiply two 16-bit signed integer numbers and returning a 32-bit result.

s.imulex8

Primitive to multiply two 8-bit signed integer numbers and returning a 16-bit result.

s.imulom16

Primitive to multiply two 16-bit signed integer numbers with overflow and underflow checks. On overflow, the maximum positive 16-bit signed number is returned as the result. On underflow, the maximum negative 16-bit signed number is returned as the result.

s.imulom8

Primitive to multiply two 8-bit signed integer numbers with overflow and underflow checks. On overflow, the maximum positive 8-bit signed number is returned as the result. On underflow, the maximum negative 8-bit signed number is returned as the result.

s.imulul6	Primitive to multiply two 16-bit signed integer numbers returning the upper 16 bits as the result.
s.imulu8	Primitive to multiply two 8-bit signed integer numbers returning the upper 8 bits as the result.
s.in	Routine to set the timed block flag.
s.issuecond	Routine to send condition-type output.
s.issueopcnd *	Primitive to define an optically isolated digital output.
s.issuevent *	Primitive to send event-type output.
s.jmpf	Routine to branch on false condition.
s.jmpt	Routine to branch on true condition.
s.le	Determines if argumentl is less than or equal to argument2 for 8- or 16-bit numbers.
s.loc	Routine to define a label.
s.lt	Determines if argumentl is less than argument2 for 8- or 16-bit numbers.
s.main	Primitive for software initialization. Sets event, port, rom and ram pointers and calls hardware processor primitive and software heading primitive.
s.monitor	Primitive to define the p2 monitor as controller supervisor.
s.mul	Primitive to multiply two 8- or 16-bit unsigned integer numbers without error checking. Returns 8- or 16-bit results.
s.ne	Determines if argumentl is not equal to argument2 for 8- or 16-bit numbers.
s.nfadd	Routine to perform numeric data processor implemented floating point addition.
s.nfdiv	Routine to perform numeric data processor implemented floating point divide.

s.nfmul	Routine to perform numeric data processor implemented floating point multiplication.
s.nfsub	Routine to perform numeric data processor implemented floating point subtraction.
s.ni	Primitive to clear timed block flag.
s.nopck	Routine to handle overflow and underflow conditions resulting from 8087 NDP arithmetic operations.
s.not	Performs 8- or 16-bit logical 'not'.
s.or	Performs 8- or 16-bit logical 'or'.
s.perform	Routine to invoke a procedure.
s.proc	Used to define a procedure entry point.
s.relayout *	Primitive to define a relay output.
s.restans *	Primitive to define a resistance transducer.
s.senscontac *	Primitive to sense a contact closure.
s.sensecond	Primitive to detect condition-type input.
s.sensevent *	Primitive to detect an event-type input.
s.senshotct *	Primitive to detect a hot contact.
s.sensopcond *	Primitive to define an optically isolated condition input.
s.sensopevt *	Primitive to define an optically isolated event input.
s.start	Dummy start primitive.
s.sub	Primitive to subtract two 8- to 16-bit numbers.
s.tabaccp2	Subroutine to add routine access for contingency/task pair.
s.tabend	Defines the end of the monitor table.
s.tabent	Primitive to add an entry to the monitor table.

s.temp	* Primitive to define temperature measurement channel.
s.var	Routine to define storage for 8- or 16-bit integer variable.
s.whend	Primitive marking the end of a while-do statement.
s.whilecon	Primitive to generate a while-do condition section head.
s.xor	Perform 8- or 16-bit logical 'exclusive or'.

APPENDIX B

LIST OF GLOBAL VARIABLES

The following global variables list is used by the realization library given in Appendix C. This list incorporates all the global variables used in the 8080 and 8086 libraries, allowing compatibility between the two and thus not requiring any user intervention in system choice of microprocessors selected during system generation. The value in parenthesis following each variable is its initial value.

CN	(0)	Counter for capacitor reference designator.
CNT	(0)	Counter for use during calculation in the fixed wait primitive.
CRN	(0)	Counter for diode reference designator.
CWORD	(0)	Flag for loading 8087 NDP control word (8086 Library only).
DIV	(0)	Flag indicating inclusion of division subroutines.
EVADDR	(0)	Event address.
EVPNT	(0)	Event pointer.
FLT	(0)	Flag indicating the use of floating point processor.
ICN	(0)	Counter for integrated circuit reference designator.
INE	(1)	Element counter for multi-element invertor.
INN	(0)	Reference designator for multi-element invertor.
INPORT	(0)	Pointer to next available input port.
ISCE	(1)	Element counter for bit slice output port.
ISCN	(0)	Reference designator for bit sliced output port IC.
ISCP	(0)	Pointer to bit sliced output port.

ISNE (1)Element counter for multi-element Schmitttrigger invertor. (0) Reference designator for multi-element ISNN Schmitt-trigger invertor. JAASE (1) Element counter for bit sliced I/O connector. JAASN (0) Reference designator for bit sliced I/O connector. Element counter for multi-element J/K JKE (1)flip-flop. Reference designator for multi-element J/K JKN (0) flip-flop. JN (1) Counter for connector reference designator. Counter for relay reference designator. KN (1)LATFLG (0) Flag for pulse event inputs requiring latching. MEM (0) Pointer used in ROM/RAM partition. MPRTA (0)Pointer to data I/O port of hardware floating point processor. (0) Pointer to control I/O port of hardware MPRTB floating point processor. MUL (0) Flag indicating inclusion of multiplication subroutines. (1) Element counter multi-element 2 input NBE nand gate. NBN (0) Reference designator for multi-element 2 input nand gate. NCE (1)Element counter for multi-element 3 input nand gate. Reference designator for multi-element 3 NCN (0) input nand gate. NDE (1)Element counter for multi-element 4 input nand gate.

Reference designator for multi-element 4 (0)NDN input nand gate. ODT (0) Flag for use of debugging package (8080 Library only). (-1) Pointer to next available output port. OUTPRT (1)Element counter for multi-element PDE peripheral driver. PDN (0)Reference designator for multi-element peripheral driver. (1) Element counter for multi-element resistor RABE pack. RAMPTR (0) Pointer to next address in RAM. RN (1)Counter for resistor reference designator. ROMPTR (0)Pointer to next address in ROM. RPN (1)Counter for resistor pack reference designator. Element counter for multi-element RS-232C RSDE (1)driver. RSIC (0)Reference designator for multi-element RS-232C driver. RSRIC Reference designator for multi-element (0) RS-232C receiver. Element counter for multi-element RS-232C RSRE (1)receiver. SCRTCH (0) Scratch register. (0)SSCHE Element counter for bit sliced input port. SSCP (0) Pointer to bit sliced input port. TMBLCK (0) Flag for timed block.

Total count of event type inputs.
